Experiment 8

Case Study on the Business Impact of a No-Code Application Implementation

1. Aim

To analyze how implementing a no-code application can improve a business process and how its impact can be measured.

2. Objectives

- Identify a business problem that can be addressed with a no-code application.
- Map the existing process and propose a digital workflow.
- Evaluate expected benefits, risks, and implementation costs.
- Define measurable indicators for assessing business impact.

3. Requirements

A sample business process, stakeholder requirements, and a no-code platform trial or product documentation.

4. Theory

No-code applications can digitize forms, centralize records, automate notifications, and provide dashboards without requiring a full custom software project. Business impact should be measured using baseline and post-implementation indicators such as processing time, error rate, visibility, staff effort, and user satisfaction. Benefits are not automatic: poor data quality, weak access controls, inadequate training, and platform limits can reduce value. A pilot and feedback cycle help ensure that the application improves the real process rather than simply reproducing existing inefficiencies.

5. Procedure

1. Choose a process with repetitive data entry, approvals, or reporting delays.
2. Document the current steps, responsible roles, common errors, and approximate completion time.
3. Design a no-code form, central data table, workflow, and report suited to the process.
4. Test with a small group using realistic but non-sensitive sample data.
5. Measure the same indicators before and after the pilot.
6. Collect user feedback, address issues, and decide whether to expand the solution.

6. Case Study and Analysis

A small maintenance company receives equipment-repair requests through phone calls, messaging apps, and paper notes. Requests are sometimes lost, managers cannot easily see pending jobs, and monthly reporting takes several hours. The company pilots a no-code application with a request form, a centralized request list, status fields, assignment notifications, and a dashboard. Staff submit requests through a consistent form; a supervisor assigns a technician and updates the status; management views open, completed, and overdue jobs. To evaluate impact, the company records the average time from request submission to assignment, the number of missing fields, the number of overdue requests, and the time needed to prepare a monthly report. It compares these measures with the baseline after several weeks. The case illustrates how a modest application can improve visibility and accountability. However, the company must define who can view customer information, train employees, maintain the workflow, and plan for exporting data if it later changes platforms. The figures should be measured during the pilot rather than assumed in advance.

7. Result / Discussion

The proposed implementation provides a consistent intake process, shared status tracking, automated notifications, and a dashboard. Its actual impact can be assessed through baseline and post-pilot measurements.

8. Conclusion

No-code implementation creates business value when it solves a clearly defined process problem and its results are measured. Governance, user adoption, and ongoing maintenance remain important.

9. Precautions / Best Practices

- Use fictional or non-sensitive test data during practice.
- Verify settings and results before using the application or configuration in a real environment.
- Record observations clearly and follow the platform's current documentation, security, and access-control guidance.
